A/B Test Plan: Georgie's Pawsitive Pet Care

The experiment will take place on the Pet Sitter — Iowa City page. Version A will be the current page without a personal photograph of Georgie, and Version B will contain one photograph of Georgie added to the Meet Georgie section. The photograph will be the only difference between the two versions. All text, headings, buttons, and other page elements will remain identical.

Adding a personal photograph of Georgie will increase the likelihood that potential customers will contact the business. Seeing the person who will care for their pets may help visitors develop trust, feel more comfortable, and create a personal connection with the business.

AI visitors will represent Iowa City pet owners looking for dependable in-home pet-sitting services. Each visitor will be given the same persona and exact prompt in a fresh conversation.
Model and version: ChatGPT (GPT-6)
All trials will use the same model and settings. Visitors will be randomly assigned using a coin flip to Version A or Version B before each trial.
Exact Prompt: "You are an Iowa City resident who owns a dog and is planning a weekend trip. You need to find a dependable in-home pet sitter to care for your dog while you are away. You are researching local pet-sitting businesses. You want to feel comfortable with the person entering your home and caring for your pet. Visit and review this website: https://gslange.github.io/pet-sitting/index.html After reviewing the website, would you feel comfortable contacting this business to arrange a meet-and-greet for your pet? Answer YES or NO, followed by one sentence explaining your decision."

The primary outcome will be whether the visitor would contact the business to arrange a meet-and-greet. Responses will be recorded as YES or NO.

The experiment will include 100 total trials: 50 for Version A and 50 for Version B. Data collection is expected to be completed by November 24, 2026.

The percentage of YES responses will be calculated for each version. The difference in contact interest will be compared using a statistical test of proportions to determine whether the difference could be due to chance. The hypothesis will be supported if Version B produces a higher contact rate than Version A, with statistical evidence that the difference is unlikely to be due to chance.
